

The weather continued to remain cooperative to the observers in July. A short glimpse at the tables shows, that there are hardly any bigger „holes“ in the monthly statistics, i.e. that there were continuously good observing conditions. This is also reflected by the fact, that more than 2/3 of the 77 cameras were active in twenty or more observing nights. With 69 active cameras, July 3/4 was the best night.

Despite the good conditions, the outcome was only comparable to July 2012 but fell clearly short of the totals of the previous year. More than 6,700 observing hours are 15% less than in July 2013, and the overall number of meteors reduced by the same percentage to 30.000.

With the alpha Capricornids and Southern delta Aquariids, July offers two well-known meteor showers that peak at the end of the month. The activity interval of the Capricornids lasts from early July to mid-August, but only at the July/August border the rates stand clearly out of the sporadic background. Figure 1 shows the activity profile of the last four years (computed with $\gamma=1.5$), which shows significant variations with respect to the peak flux density. Whereas in 2013 and 2014 identical values of about 2 meteoroids per 1,000 km² and hour were reached, it was clearly less in 2011 (resp. the peak occurred earlier) and with 2.5 meteoroids clearly more in 2012.

Figure 1: Flux density profile of the alpha Capricornids, obtained from IMO network video observations 2011-2014.

If all four profiles are averaged, we obtained the expected smooth graph with an activity plateau between 125 and 130° solar longitude (figure 2). Note that we obtained a similar profile already in our 2009 meteor shower analysis, but there the plateau occurred between 120 and 125° solar longitude. Did the Capricornids arrive late in the past few years (which would explain the early peak in 2011)? Looking at the MDC shower list we find five parameter sets all referring to solar longitude 127°, which corresponds to the current activity profile.

Figure 2: Flux density profile of the alpha Capricornids, averaged over the years 2011-2014.

The population index was not easy to determine. The 2014 data alone with less than 100 Capricornids per night were not sufficient to obtain reliable values. If the observations from 2011 to 2014 are combined, however, we have a data set of 300 to 500 Capricornids per night, which yields a good r-value for most nights. The curves in the diagram that depict the dependency of the flux density from the population index for different limiting magnitudes often intersect at a single point (e.g. on July 26/27, figure 3 left). The overall profile (figure 3, right) presents another surprise, since the population index increases almost all the time. It starts with values from 2.5 and reaches a minimum of 1.7. So maybe the Capricornids show some mass sorting effect like the Geminids, such that the percentage of larger meteoroids after the peak is higher than before the peak. The visual handbook of IMO lists a population index of $r=2.5$ and points out that many bright alpha Capricornids can be seen.

Figure 3: Flux density vs. population index for different limiting magnitudes on July 26/27 (left) and the complete population index profile of the alpha Capricornids (right), obtained from IMO network data of 2011 till 2014.

The Southern delta Aquariids are active from mid-July till mid-August. Also here we find variations in the peak flux density, whereby 2011 is a lower outlier with just 15 meteoroids per 1,000 km² and hour and the years 2012 till 2014 yield peak rates between 30 and 45 (figure 4).

Figure 4: Flux density profile of the Southern delta Aquariids, obtained from IMO network video observations 2011-2014.

The averaged flux density profile shows the well-known asymmetric shape where the descending branch is shallower than the ascending. Even at the Perseids' peak, the shower still stands out from the sporadic background.

Figure 5: Flux density profile of the Southern delta Aquariids, averaged over the years 2011-2014.

There were more data available to calculate the population index profile of the Southern delta Aquariids – between 200 and 1,000 meteors per night if the observations from the last four years are combined. In some cases the intersection point was well defined again (e.g. on July 28/30, figure 6 left), but in others it was not.

The overall population index profile (figure 6, right) has a different shape than the profile of the Capricornids. Here the value wobbles around 2.0 and reaches smaller figures of 1.75 towards their maximum at the end of July. Unfortunately the profile ends at July 31, since the August data of 2014 are not yet processed. Still there is a large discrepancy compared to the data given in the IMO handbook: With $r=3.2$ the Southern delta Aquariids have the biggest population index of all IMO working list of meteor showers, i.e. they shall have a bigger fraction of faint meteors than any other shower and the sporadic meteors. That cannot be confirmed from our data, however.

Figure 6: Flux density vs. population index for different limiting magnitudes on July 26/27 (left) and the complete population index profile of the Southern delta Aquariids (right), obtained from IMO network data of 2011 till 2014
