June was another highlight for most observers of the IMO network. If we forget about a short rainy period right before midsummer, most observers enjoyed perfect conditions through all of June. 12 cameras recorded meteors in twenty and more nights, and even though the data from five cameras are still missing at this point, we managed to obtain another all-time high for June with more than 1,700 hours of effective observing time and 6,000 meteors. Among the months with least observations, June could join up. In soccer we would say, that the relegation spots are held by February (24,558 meteors), May (24,395 meteors) and June (24,362 meteors). When the currently missing data are added, June will probably pass the other two months. Once more, that

is in particular thanks to Steve Kerr, who took full advantage of the high meteor activity and long nights in the southern hemisphere.

On June 24, Javor Kac reported enhanced June Bootid activity to the IMO News mailing list, which Slovenian observers had noted during a comet observing session between 0 and 1 UT. Also his own camera ORION1 had recorded more JBO than SPO this night. He alarmed other observers to give this shower special attention, but there were no further positive reports. Some visual observers even noted that they had observed nothing special on June 23/24. So was that just a false alarm?

To answer this question, the video data between June 21/22 and 29/30 were analysed in detail. At first, we calculated the ratio between the number of June Bootids and Sporadics over all cameras for each night. The result, which is based on a total of 1889 SPO and 141 JBO, is given in Figure 1. The observation of Javor is clearly confirmed: Whereas the June Bootids were virtually absent all of the time, we recorded over a hundred shower meteors on June 23/24 alone, which is about 1/3 of the sporadic count of that night. The ratio of Anthelion to sporadic meteors is plotted for comparison. As expected, the Anthelion rate was almost constant in that time interval. Whereas the regular June Bootid maximum was predicted for June 27, we observed an early outburst of this shower similar to 2004. Only the ZHR stayed probably below 10 this time.

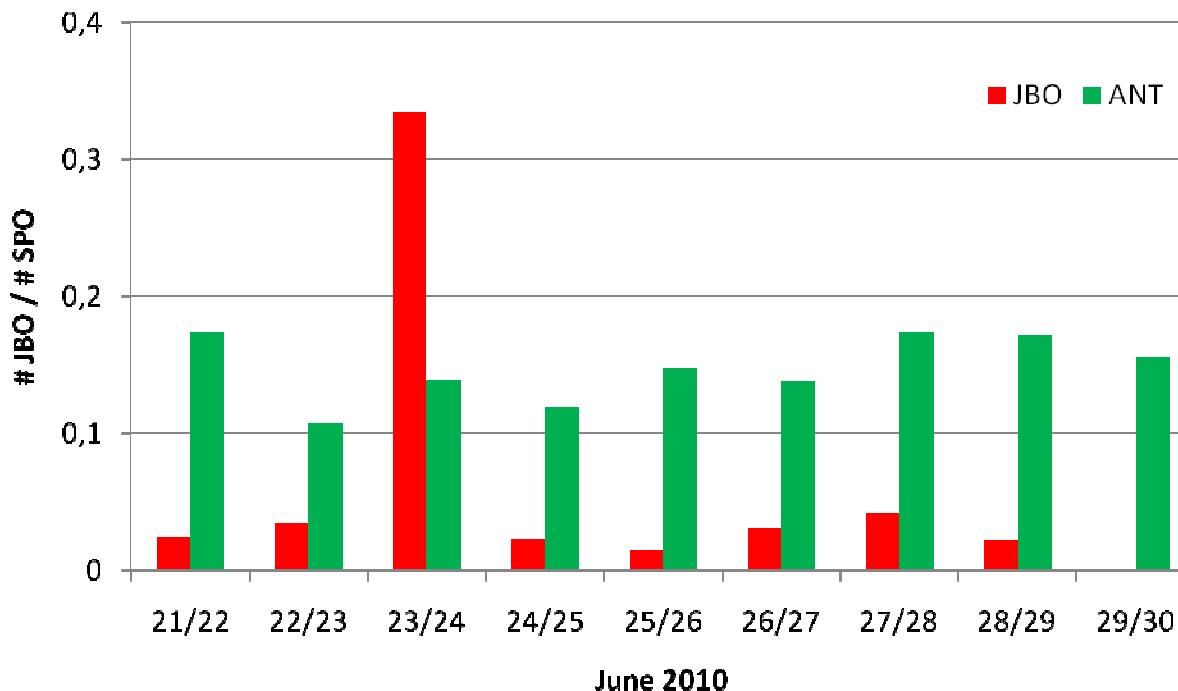

Figure 1: Activity profile of the June Bootids in the third decade of June 2010 (red). The enhanced JBO rate of June 23/24 is clearly visible. For comparison, the activity profile of the Anthelion source is given as well (green).

Next we analysed, whether the activity on June 23/24 was constant, or whether there were strong variations as suggested by some observers. Fortunately just that night was the best June night ever (for the first time we collected more than 100 hours effective observing time), so that we could analyze the number of June Bootids in half hour intervals and correct the counts for the radiant altitude. The resulting profile is given in figure 2. There might be a dip in activity between 21:00 and 22:30 UT, but overall the JBO activity was clearly enhanced all night long.

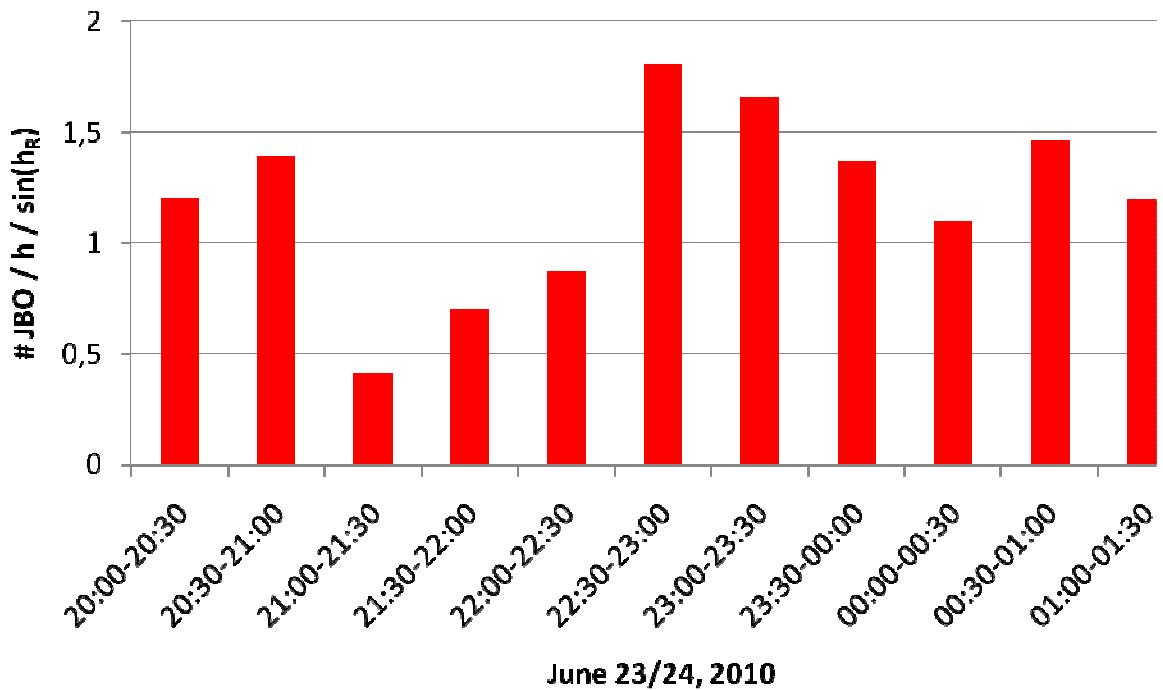

Figure 2: JBO activity on June 23/24. Here, the average hourly number of June Bootids, corrected by the radiant altitude, is given.

Finally, we derived the radiant position of the June Bootids from the observation of that single night. With $\alpha=224^\circ$, $\delta=48^\circ$ and $v_{inf}=17\text{km/s}$ we received figures that match almost perfectly to the values given in the IMO shower calendar. Reports from observers, who noted the radiant about 10 degrees farther south in previous years, could not be confirmed for 2010.

Away from the JBO and ANT, there are just two other showers in June. Both, the delta Piscids (410 DPI) and f-Ophiuchids (412 FOP) were detected in our shower analysis last year, which is why we wanted to check if they were traceable in 2010, too. We extended the shower list by these showers and recomputed the meteor shower assignment for all observations starting from June 19. Between June 19 and 26, a total of 48 meteors were assigned to the delta Piscids. The activity was such low that they did not stand out of the sporadic background. Only on June 21/22 we recorded a slightly larger number of 16 delta Piscids. With only 31 meteors fitting to the radiant, the f-Ophiuchids remained below the detection threshold all the time between June 26 and 30.
