

Results of the IMO Video Meteor Network – May 2014

Sirko Molau, Abenstalstr. 13b, 84072 Seysdorf

2014/09/05

The pleasant spring weather continued in May 2014. Everywhere in Europe the observers could enjoy many clear nights. 75 video systems were active on May 5, and 47 out of the overall 81 cameras managed to obtain observations in twenty or more observing nights. Enrico Stomeo missed only one night with his camera SCO38, and Carl Hergenrother (who is currently on top of the 2014 observing statistics with a margin of five nights) had to pause just two nights with his camera SALSA3. Under such excellent conditions it's no surprise that we collected almost 7,500 hours of effective observing time, which is a 20% plus compared to the previous best May 2012. With over 18,000 meteors, also the meteor count increased by 20% compared to 2012.

There were no new cameras in May, but Maciej Maciejewski provided most of his video equipment for a Camelopardalid expedition to Canada. Everyone knows that the hoped-for outburst did not materialize (at least not for visual and video observers) - still it is worthwhile to have a quick look at the collected data. Peter Brown reported that the Camelopardalids were prominent in the Canadian CMOR radar, which confirms the predicted outburst. However, most recorded echoes were underdense, i.e. the outburst was rich in faint meteors. Based on the IMO quick-look analysis, the peak ZHR hardly reached 20, and also the meteor cameras in America recorded only few shower meteors. Even the airborne campaign of Peter Jenniskens had to content with roughly 20 Camelopardalids, and also the full IMO network could record only about 30 shower members on May 23/24. It is impossible to obtain an activity profile from such a small data set.

Better visible were the eta Aquariids and eta Lyrids. The first shower is always challenging for the observers in the IMO network, because for most of the cameras it becomes visible only in morning twilight and most meteors are recorded at low radiant altitudes.

Let's first look at a summary profile with low temporal resolution, calculated from over 5,000 eta Aquariids recorded in the last four years (figure 1). It shows an almost symmetric profile with a peak at 46.3° solar longitude and a peak flux density of almost 50 meteoroids per $1,000 \text{ km}^2$ and hour (at $\gamma=1.5$).

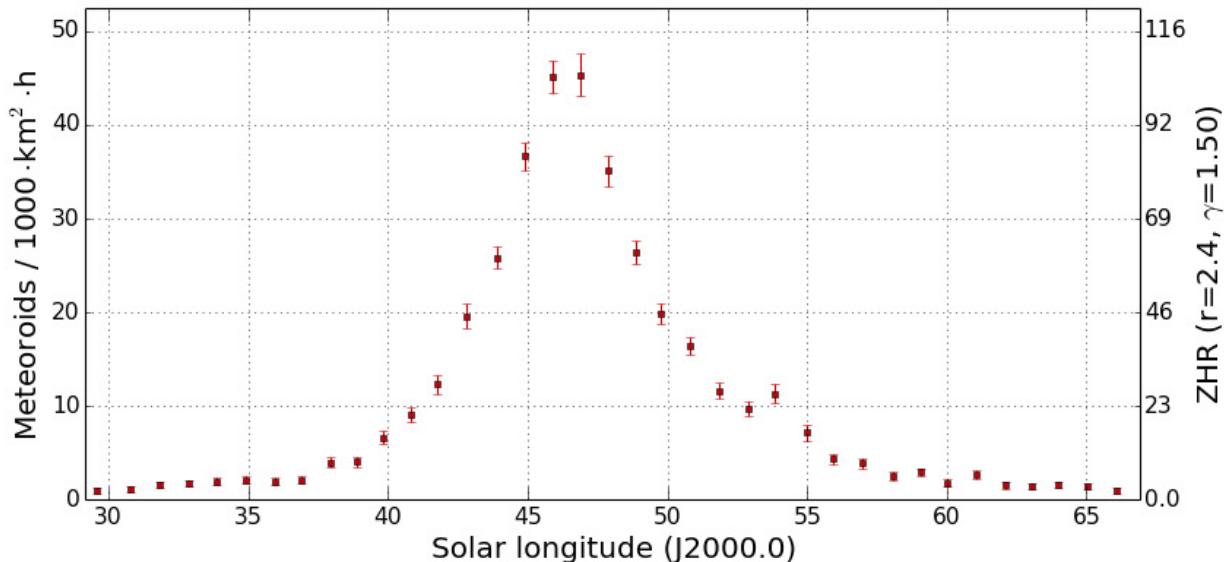

Figure 1: Overall activity profile of the eta Aquariids from flux density measures in the IMO Video Meteor Network 2011 till 2014.

Looking at the individual years, the picture becomes more differentiated (figure 2). The unusual peak of 2013 is easily visible, and so is a shift of the 2014 activity profile. Both the ascending and descending activity branch were a little later in this year than in the previous.

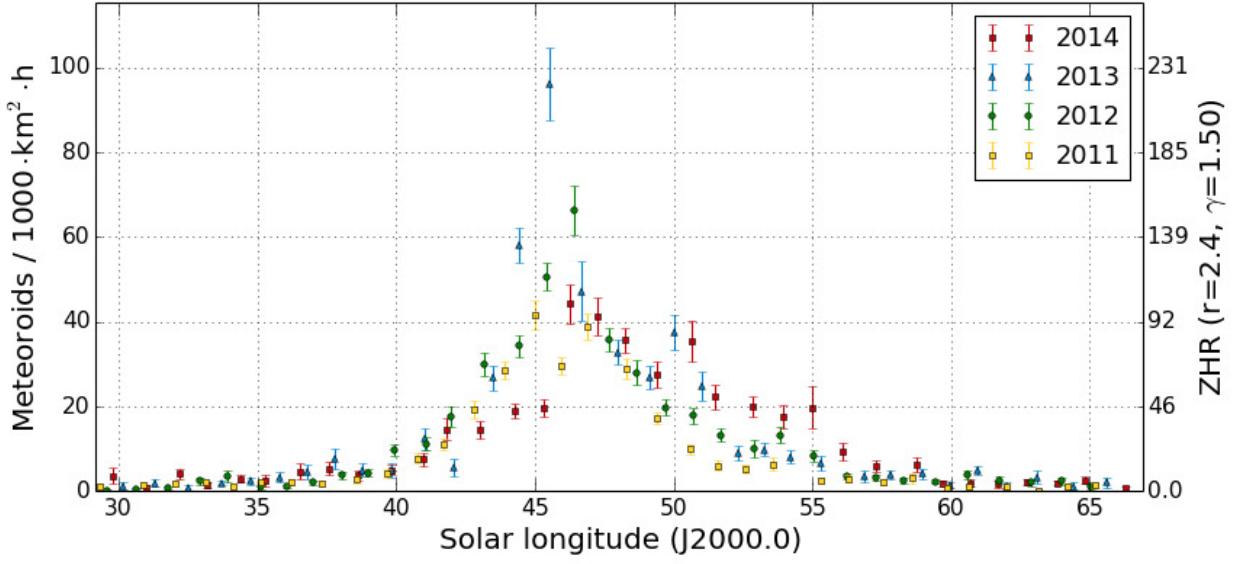

Figure 2: Activity profile of the eta Aquariids, separated for the years 2011 till 2014.

The limits become visible in a high resolution graph of the 2014 peak (figure 3). Whereas there is only little scatter at the begin of the observing window, when the radiant is lowest in the sky, the rates increase rapidly towards the end of the observing window. That cannot be explained by the zenith exponent, since it has the biggest impact on the first few intervals. As the effect was not observed in previous years it can be speculated, that this is just a selection effect (i.e. that other cameras dominated at the end of the night than at the begin). Unfortunately, the fluxviewer has currently not the options to select or reject individual cameras to easily substantiate this hypothesis.

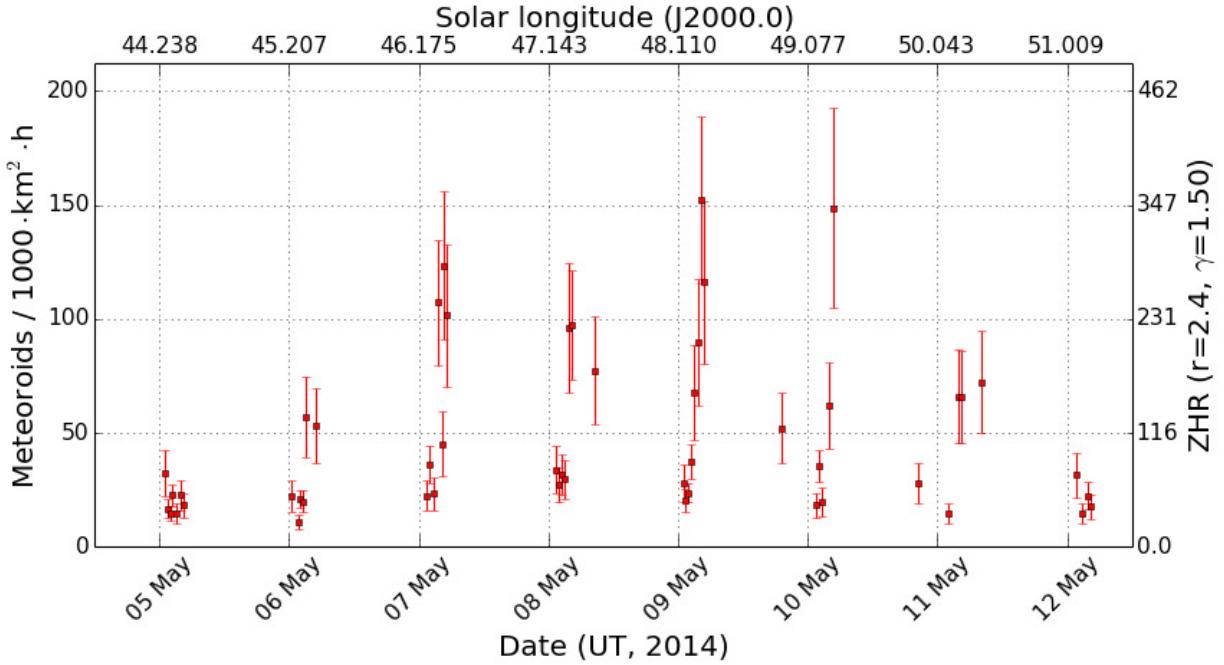

Figure 3: High resolution activity profile from the peak of the eta Aquariids in 2014.

The eta Lyrids, which are active only a few days later, show an unusual activity profile. It is consistent over the last four years and statistically on quite solid ground with meanwhile over 1,000 shower members. Up to a solar longitude of 49° , the shower hardly stands out from the sporadic background. Thereafter the flux density jumps suddenly by a factor of two, but instead of a clear peak, the activity remains almost constant for over two days (figure 4). With some fantasy, the averaged activity profile yields a peak at 49.4° solar longitude (figure 5).

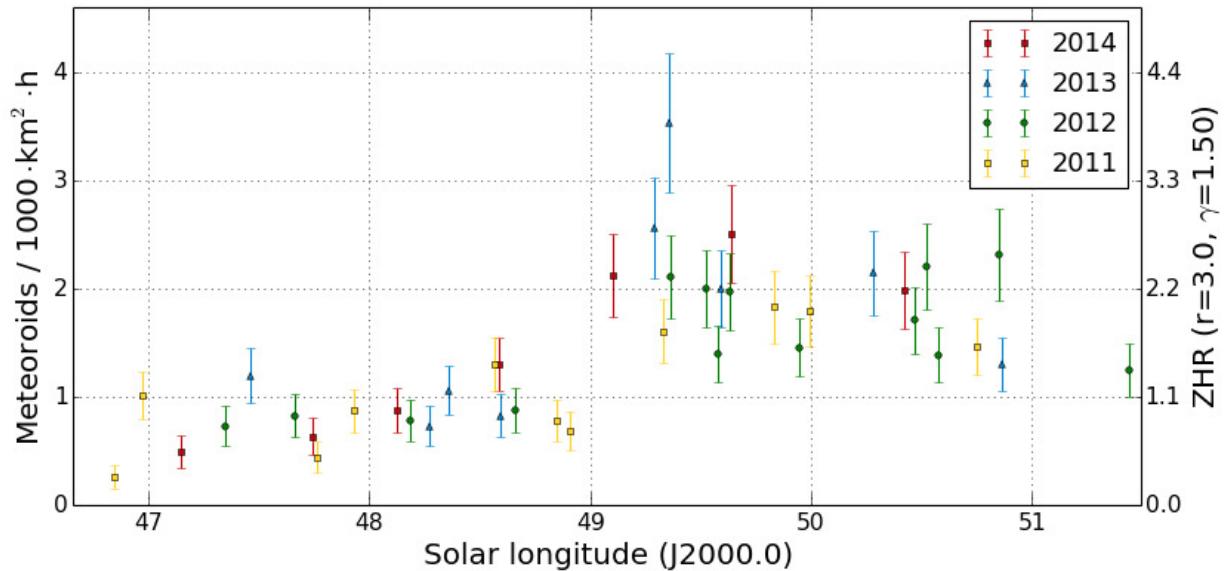

Figure 4: Activity profile of the eta Lyrids, separated for the years 2011 till 2014.

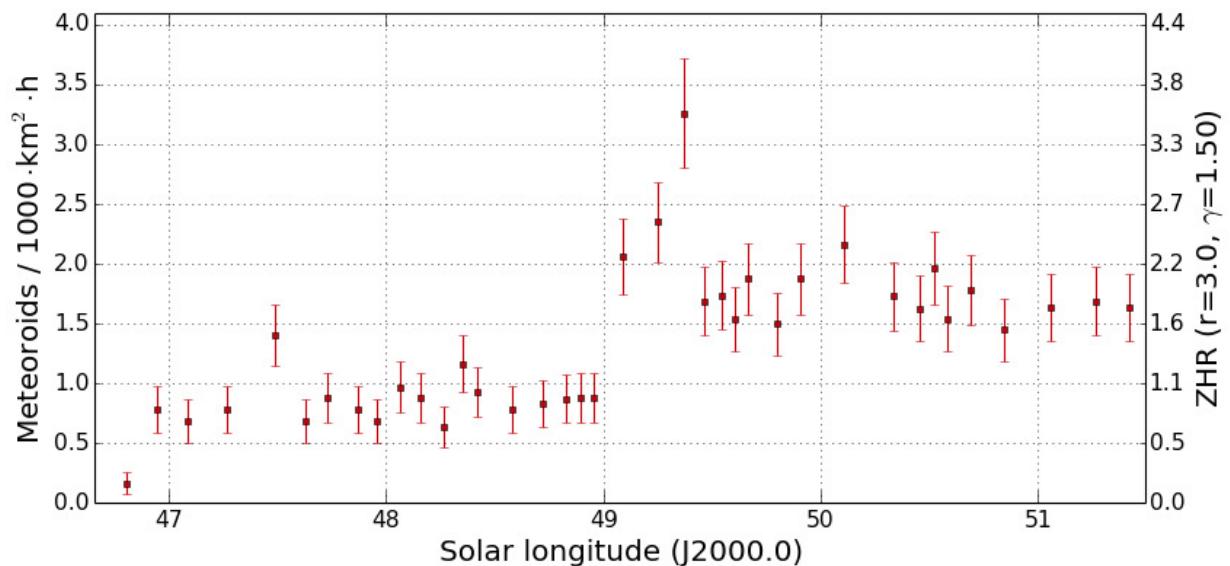

Figure 5: Overall activity profile of the eta Lyrids from data between 2011 and 2014.
