

Results of the IMO Video Meteor Network – January 2017

Sirko Molau, Abenstalstr. 13b, 84072 Seysdorf

2017/07/12

The year starts with long nights for the IMO video observers, but also with typically poor observing conditions. This year the weather was mediocre but still above par for a January which led to the best January output in the history of the IMO network. We counted a total of 77 active cameras, half of which with twenty or more observing nights. On January 6 and 21 we had 65 cameras in operation. The effective observing time summed up to almost 11,900 hours, which is 2,000 more than in the previously best January 2012. With over 33,000 meteors we recorded 10% more than in 2012.

There was no new camera, but operation of the Italian camera JENNI was taken over by Francesca Cineglosso at the begin of year.

To get a nice display from the most important meteor shower of January, which is also the last major shower for the next half year, you need three prerequisites: a convenient lunar phase, pleasant weather and a peak in the European night time hours. The first two conditions were given in 2017, but the peak fell into the noon hours UT of January 3. So we could only observe the increase in rates in the night before, and the decrease in the night after the peak. The peak activity as such could not be recorded by us (figure 1).

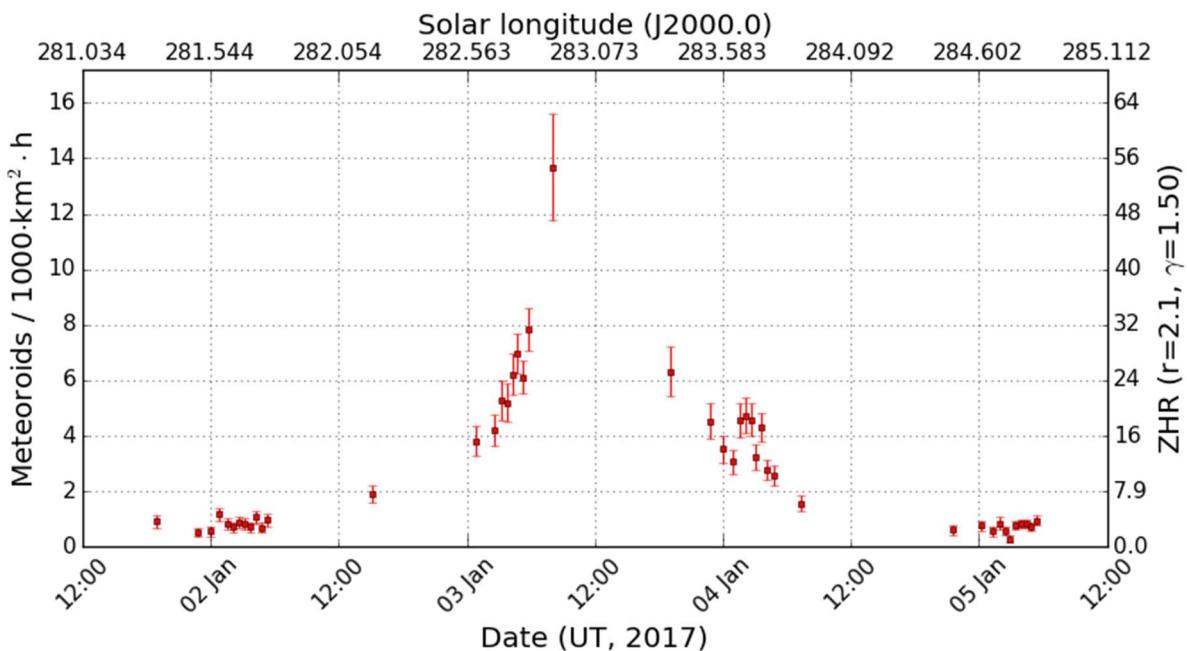

Figure 1: Flux density profile of the Quadrantids in January 2017, derived from video data of the IMO Video Meteor Network.

It is difficult to estimate the strength of the peak from these data, but the ascending and descending branches were similar to the data set of 2012 and 2015, when the activity was below the average (figure 2). That fits to visual observations. The automated analysis of visual data at the IMO homepage yields a peak ZHR of 80 – in vintage years the ZHR may reach values twice as high!

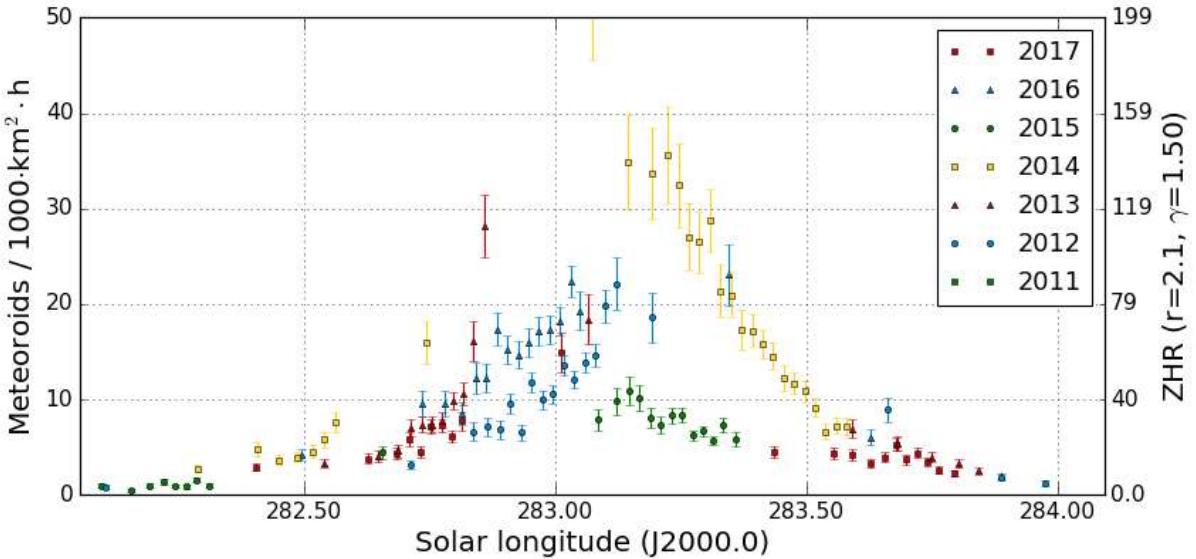

Figure 2: Comparison of the flux density profile of the Quadrantids 2011 till 2017.

In 2015, the Canadian CMOR radar detected a short, but intense outburst of the kappa Cancriids. Unfortunately, also the peak of this shower at 289.3° solar longitude fell into the European daytime hours. We re-calculated the meteor shower assignment on January 9 and 10, anyway, but the activity of the shower remained negligible as expected.

Also the gamma Ursae Minorids were checked in detail. This minor shower was discovered by CMOR in 2010 and could be detected visually last year, even though video observations evidenced only a low activity level near the detection limit. That picture has not changed in 2017. Once more we measured a flux density below one meteoroid per $1,000 \text{ km}^2$ and hour at 299° and 300° solar longitude (figure 3). That is equivalent to a ZHR below one.

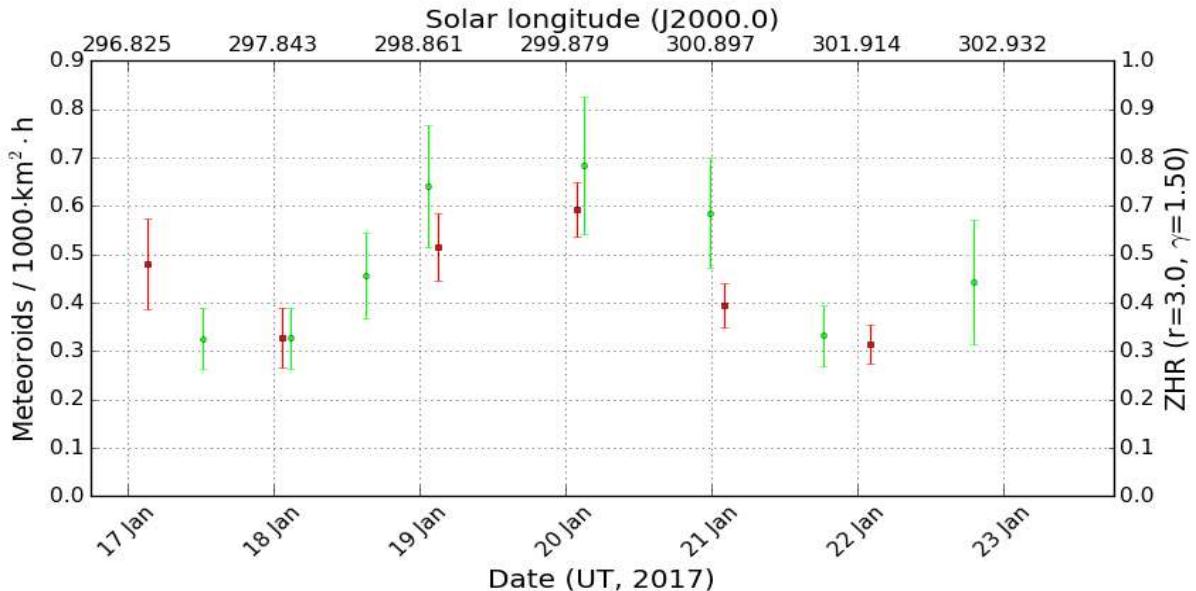

Figure 3: Comparison of the flux density profile of the gamma Ursae Minorids in 2016 (green) and 2017 (red).

Surprisingly even such a weak shower presents a high-quality activity profile with only little scatter. Not so much the absolute activity level but rather the effective collection area of the camera network is essential here, and in this respect the shower seems well positioned with its circumpolar radiant and the long January nights. How good the conditions really are was verified

with a simple experiment. We compared the typical effective collection area of the gamma Ursae Minorids with some major shower (QUA, ETA, PER, GEM). In order to get a representative picture, we calculated the total collection area of the four cameras REMO1-4 (which point in all four directions at about 45° altitude) near Berlin under normalized observing conditions (constant limiting magnitude of 6.3 mag) for the peak night of each shower.

It is no surprise that the Geminids yield a perfect result, since their radiant is well positioned in the long December nights. However, surprisingly the Quadrantids perform a few percent better, even though they are typically not observed before midnight. At 52° northern latitude, the radiant is circumpolar and has even at the lower culmination an altitude of more than 10°. It is not too far away from the center of field of view of the cameras, which causes a lower angular meteor velocity, and at dawn the radiant lies close to the zenith.

With over 34,000 km² and hour, the collection area of the gamma Ursae Minorids is 1/3 smaller than that of the Geminids, and the collection area of the Perseids even only half of it. For comparison: The eta Aquariids accumulated less than 1,000 km² and hour in this experiment!

It is also noteworthy how the cameras perform in comparison to each other. REMO1 observing eastward has always the biggest effective collection area, since the combination of radiant altitude and distance from center of field of view is best here. In case of the Quadrantids, Perseids and eta Aquariids, the other three cameras have about the same collection area. During the Geminids, the northward directed camera REMO3 is clearly inferior of the southward oriented REMO2 and westward oriented REMO4, and in case of the gamma Ursae Minorids it is just the other way round (Figure 4).

Overall the gamma Ursae Minorids are well positioned for IMO network video observers which explains the fine quality of the data set.

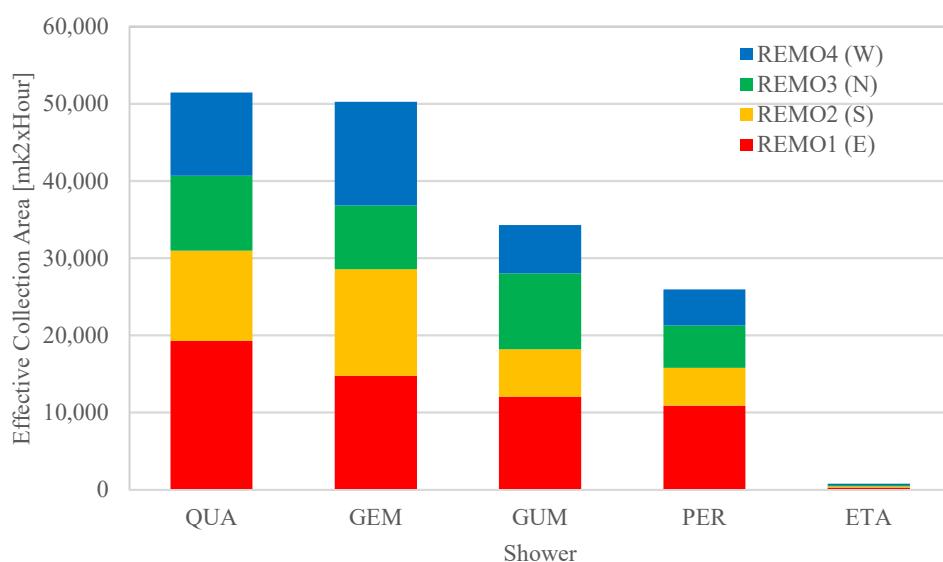

Figure 4: Effective collection area of the cameras REMO1 to REMO4 per night under normalized conditions (same limiting magnitude) for the peaks of different meteor showers.
