

Results of the IMO Video Meteor Network – January 2018

Sirko Molau, Abenstalstr. 13b, 84072 Seysdorf

2018/12/23

A spectacular year 2018 started with a meager January. With Thomas Bianchi of Italy and Henrietta Nagy of Hungary, we could win two new observers for our video network, but still the output was well below the previous years. Thomas operates the Mintron camera OMSL1 with a 4mm Tamron lens in Mt. San Lorenzo. In the previous few months, Henrietta has taken over the support for a number of meteor cameras in Hungary. Here she is listed with the new camera HUPIS, a Mintron camera with 3,8mm Computar lens installed in Piszkestető.

Overall 41 observers contributed with 80 meteor cameras to the IMO network in January 2018. The first half of the month saw longer observing gaps at all observing sites due to poor weather, in the second half at least the observers in southern Europe could observe unhamperedly. Thus, only about every third camera managed to observe in twenty or more observing nights in January. The effective observing time sums up to 8,000 hours, whereas in the previous three years we collected between 9,000 and 12,000 observing hours. With over 20,000 meteors, also the meteor yield was up to 40% smaller than in the years before.

Full moon right before the peak in combination with poor weather did not promise fine observing conditions for the first major shower of the year. In the night of January 3/4, 2018, we could record just about a thousand meteors. Figure 1 shows the activity profile of the Quadrantids. Due to their short peak, the profile is not really meaningful. It only tells us that in the aforementioned night we recorded more Quadrantids than in the nights before and thereafter. Whether we really hit the peak (which is quite unlikely given the low flux density of 10 meteoroids per 1,000 km² and hour) we only know when comparing the data with the years before.

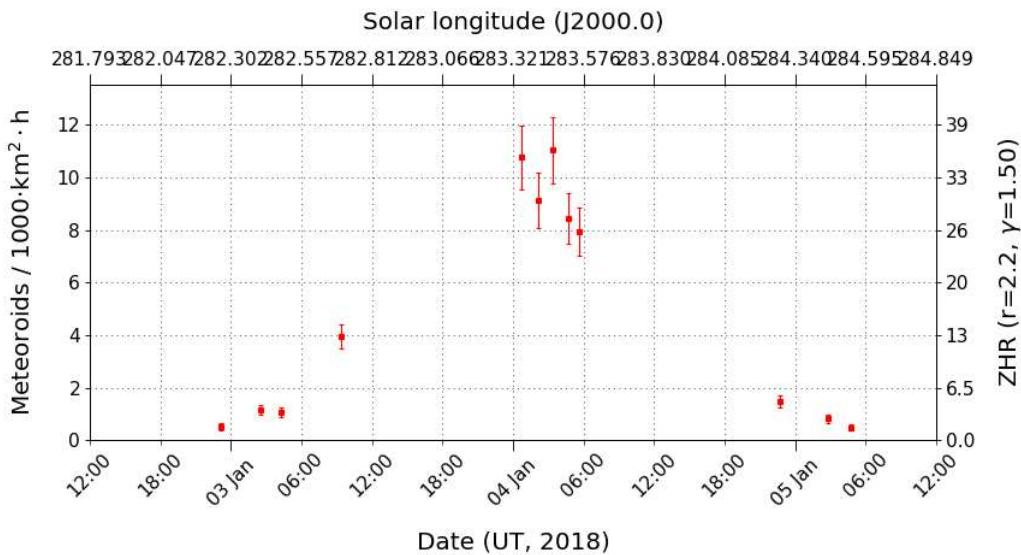

Figure 1: Flux density profile of the Quadrantids in January 2018, derived from video data of the IMO Network.

Figure 2 presents the flux density profile of the years 2015 till 2018. It shows that we indeed missed the peak in 2018. That far away from the maximum the rate was still considerable, but we should not forget that we measure higher flux density at full moon by tendency.

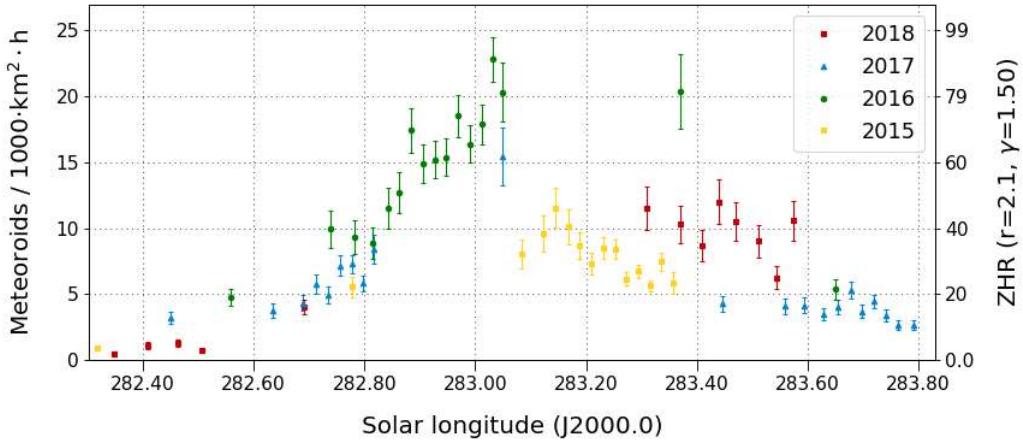

Figure 2: Comparison of the flux density profile of the Quadrantids in 2014-2017, derived from video data of the IMO Network.

The population index in 2018 was derived from about 400 Quadrantids to $r=1.7$, compared with $r=2.3$ for 200 sporadic meteors in the same time interval. That sounds plausible and matches to the values we obtained for 2013, 2014 and 2017. However, in other years, the population index differs substantially, as can be seen in figure 3. Particularly conspicuous are 2012 and 2016, when the Quadrantid peak occurred right before new moon and we measured population indices of $r=2.5$. Furthermore, the sporadic population index was particularly small in 2012 and 2015.

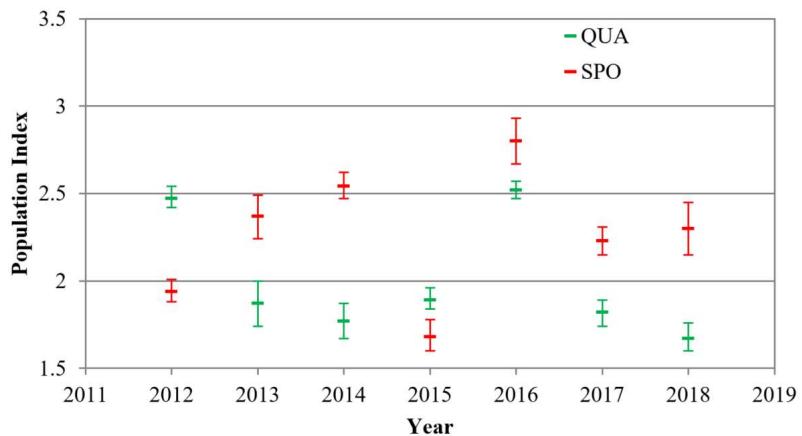

Figure 3: Population index of the Quadrantids (green) and sporadic meteors (red) in 2012-2018.

If we compute a higher resolution population index profile from all years (figure 4), this paradox it at least partially resolved. With $r=2.3$ to $r=2.0$, the population index at the begin and end of the activity period is higher than at about 283.3° solar longitude when the value decreases to $r=1.6$. Since we observe every year only a fraction of the full activity profile in central Europe, we sometimes catch regions with a higher and in other years regions with a smaller population index. For this reason, the r -values are nearly identical every four years. The remaining variations can be attributed to different observing conditions (weather, lunar phase).

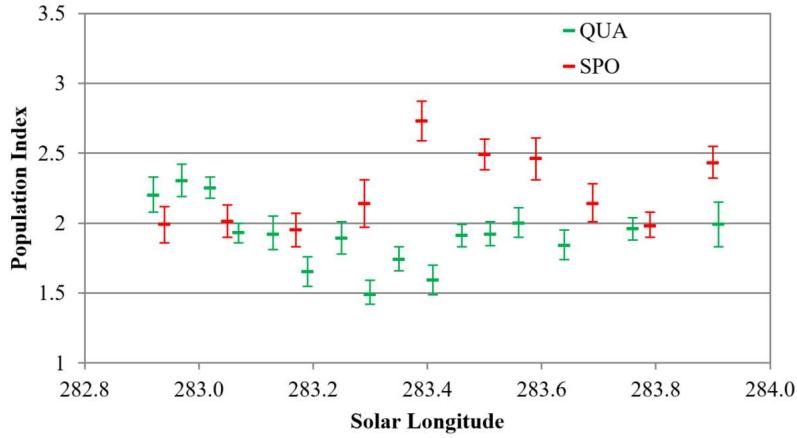

Figure 4: Higher resolution average population index profile of the Quadrantids (green) and sporadic meteors (red) in 2012-2018.

On January 9/10, 2015, we could observe an extremely short outburst of the kappa Cancriids with a FWHM of just 40 minutes. In the previous years the shower remained invisible, but the peak time was also outside the European observing window. In 2018, we reached the corresponding solar longitude of 289.315° on January 9 at 21:10 UT. That was still quite early in the night, but on most observing sites the radiant was already above 20° altitude, so that we should have an outburst of similar strength. A re-calculation of the shower assignment of all meteors yielded hardly any matches, though, which is why we can quite safely exclude another outburst in 2018.

Finally, we checked if the minor shower of the gamma Ursae Minorids was observed in 2018. The activity profile (figure 5) shows slightly enhanced rates between January 18 and 20, but the flux density remained below one meteoroid per $1,000 \text{ km}^2$ and hour. The population index was clearly smaller than the sporadic r-value, but more detailed values could not be derived due to the small data set (150 shower meteors).

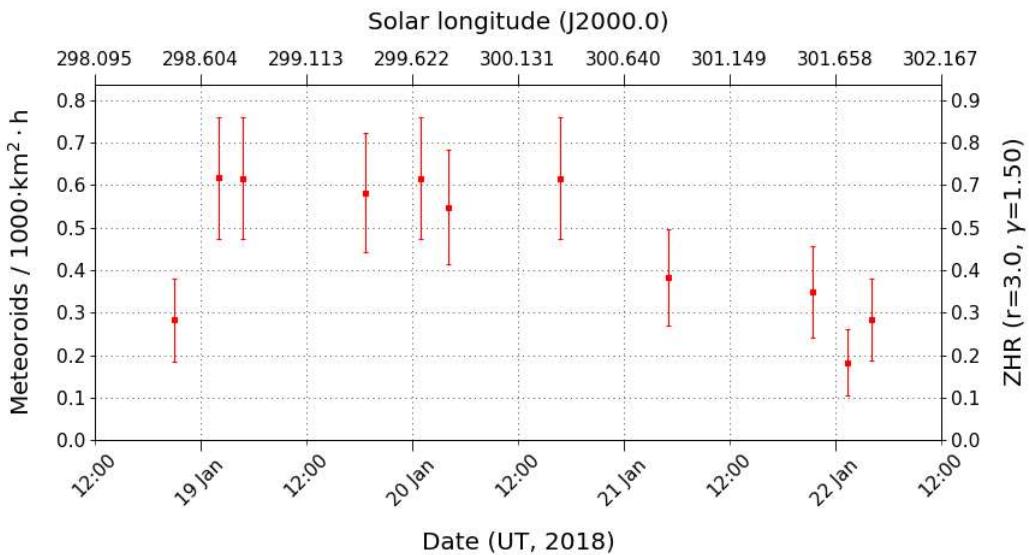

Figure 5: Flux density profile of the gamma Ursae Minorids in January 2018, derived from video data of the IMO Network.
